

# CPT 203

## Introduction

**智能工程学院**  
西交利物浦大学

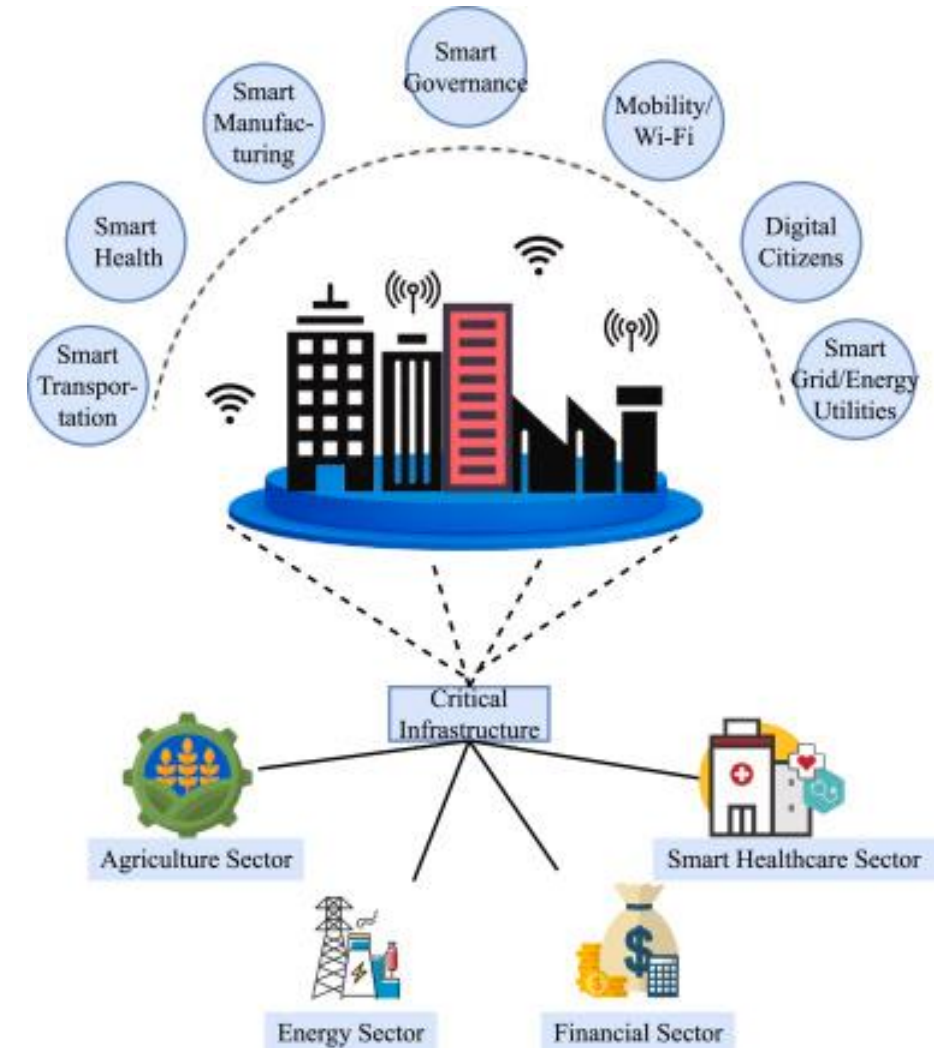

# Learning Objectives of Week 1

- To understand what software engineering is and why it is important;
- To understand that the development of different types of software systems and the required different software engineering techniques;
- To understand some ethical and professional issues that are important for software engineers

# Introduction

- We can't run the modern world without software.
  - National infrastructures and utilities are controlled by computer-based systems and most electrical products include a computer and controlling software.
  - Industrial manufacturing and distribution is completely computerized, as is the financial system.
  - Entertainment, including the music industry, computer games, and film and television, is software intensive.

# Introduction

- Software systems are abstract and intangible.
  - They are not constrained by the properties of materials, governed by physical laws, or by manufacturing processes.
- Implication? (Benefits and drawback)
  - This simplifies software engineering, as there are no natural limits to the potential of software.
  - However, because of the lack of physical constraints, software systems can quickly become extremely complex, difficult to understand, and expensive to change.

# Computer software

*Computer Software* is a collection of instructions, data, or *computer* programs that are used to run machines and carry out particular activities. Software products may be developed for a particular customer or may be developed for a general market.

Your JAVA code ?

# What is Software System?

- A software system is a system that consists of a number of separate computer software, configuration files, system documentation and user documentation. (“Wikipedia, Software system”)
- The term "software system" should be distinguished from the terms “computer software”. The term computer software generally refers to a set of instructions that perform a specific task. However, a software system generally refers to a more encompassing concept with many more components. (“Wikipedia, Software system”)
- The use of the term software system is at times related to the application of system theory approaches in the context of software engineering.

# Software Engineering

Xi'an Jiaotong-Liverpool University

西交利物浦大學

- Software engineering is an engineering discipline that is concerned with all aspects of software production.
- As a software engineer, you apply software development process when developing a software system.

# Software Engineering

- **Engineering discipline** - Engineers make things work. They apply theories, methods, and tools where these are appropriate. However, they use them selectively and always try to discover solutions to problems even when there are no applicable theories and methods. Engineers also recognize that they must work to organizational and financial constraints so they look for solutions within these constraints.
- **All aspects of software production** - Software engineering is not just concerned with the technical processes of software development. It also includes activities such as software project management and the development of tools, methods, and theories to support software production.

# Additional information

**Invention Of Software Programming**

<https://www.youtube.com/watch?v=UPAkeZBxb0I>

# Software Failure & Success

- Software engineering is criticized as inadequate for modern software development.
- Software failures are a consequence of two factors:
  - Increasing demands
  - Low expectations (you don't expect the software to grow into a giant beast)

# Professional software development

- Amateur

- People in business write spreadsheet programs to simplify their jobs
- scientists and engineers write programs to process their experimental data
- hobbyists write programs for their own interest and enjoyment

- Professional

developed for specific business purposes, for inclusion in other devices, or as software products such as

- intended for use by someone apart from its developer
- is usually developed by teams rather than individuals
- It is maintained and changed throughout its life.

A screenshot of a code editor window showing the contents of a file named HelloWorld.java. The code is written in Java and includes a package declaration, a class declaration, and a main method. The code is as follows:

```
1 package com.example.helloworld;
2
3 public class HelloWorld {
4
5     public static void main(String args[]) {
6         System.out.print("Hello World!");
7     }
8
9 }
10
11
```

# Professional software development

Xi'an Jiaotong-Liverpool University  
西交利物浦大學

- Software engineering is intended to support professional software development, rather than individual programming.
- It includes techniques that support program specification, design, validation, and evolution.
- Professional software usually has the following properties: -
  - Strict user requirements
  - Required accuracy and data integrity
  - Higher security standard
  - Stable performance for heavy load
  - Required technical support, etc.

## USER AND SYSTEM REQUIREMENTS

### User Requirements

- Written for customers
- often in natural language, no technical details

### System requirements

- Written for developers
- detailed functional and non-functional requirements
- clearly and more rigorously specified

# Professional software development

Xi'an Jiaotong-Liverpool University

西交利物浦大學

Product characteristics	Description
Maintainability	Software should be written in such a way so that it can evolve to meet the changing needs of customers. This is a critical attribute because software change is an inevitable requirement of a changing business environment.
Dependability and security	Software dependability includes a range of characteristics including reliability, security, and safety. Dependable software should not cause physical or economic damage in the event of system failure. Malicious users should not be able to access or damage the system.
Efficiency	Software should not make wasteful use of system resources such as memory and processor cycles. Efficiency therefore includes responsiveness, processing time, memory utilization, etc.
Acceptability	Software must be acceptable to the type of users for which it is designed. This means that it must be understandable, usable, and compatible with other systems that they use.

# TWO kinds of software products

- Generic software products
  - These are systems that are produced by a development organization and sold on the open market to any customer who is able to buy them.
  - Any example ?
- Customized software products
  - These are systems that are commissioned by a particular customer. A software contractor develops the software especially for that customer.
  - Any example?
- The distinction between these system product types is becoming increasingly blurred

# Software Development challenges

Xi'an Jiaotong-Liverpool University

西交利物浦大學

- Why does it take so long to get software finished?
- Why are development costs so high?
- Why can't we find all errors before we give the software to our customers?
- Why do we spend so much time and effort maintaining existing programs?
- Why do we continue to have difficulty in measuring progress as software is being developed and maintained?

# Software Deterioration

- Software is a logical rather than a physical system element. Therefore, software has one fundamental characteristic that makes it considerably different from hardware: *Software doesn't **wear out.***
- In theory, therefore, the failure rate curve for software should take the form of the “idealized curve” shown in Figure

# Software Deterioration

- Software doesn't wear out. But it does **deteriorate**
- During its life, software will undergo change. As changes are made, it is likely that errors will be introduced, causing the failure rate curve to spike as shown in the “actual curve” ( Figure 1.2 ).
- Before the curve can return to the original steady-state failure rate, another change is requested, causing the curve to spike again.

Software engineering methods strive to reduce the magnitude of the spikes and the slope of the actual curve

- To reduce software changes: -
  - Work closely with the stakeholder to ensure requirements are correctly defined
  - Improve requirement study approach to achieve better requirements study
- To reduce side effects after changes: -
  - The software should be modular so that changes will not have a lot of side effects to other part of the software
  - The software must be maintainable
  - Comprehensive testing should put in place to reduce errors.

- Software engineering is a systematic **approach** to the production of software that takes into account practical cost, schedule, and dependability issues, as well as the needs of software customers and producers.
- How this systematic approach is actually implemented varies dramatically depending on: -
  - The **organization** developing the software
  - The type of **software**
  - The **people** involved in the development process.

- Perhaps the most significant factor in determining which software engineering methods and techniques are most important is the type of application that is being developed.
- 
- |   |   |
|---|---|
| <ul style="list-style-type: none"><li>• Stand-alone applications</li><li>• Interactive transaction-based applications</li><li>• Embedded control systems</li><li>• Batch processing systems</li></ul> | <ul style="list-style-type: none"><li>• Entertainment systems</li><li>• Systems for modeling and simulation</li><li>• Data collection systems</li></ul> |
|---|---|

- The systematic approach that is used in software engineering is sometimes called a software process.
- A software process is a sequence of activities that leads to the production of a software product.
- There are four fundamental activities that are common to all software processes: -
  - **Software specification**
  - **Software development**
  - **Software validation**
  - **Software evolution**

- Different types of systems need different development processes.

For example,

- embedded control system in an aircraft has to be completely specified before development begins.
- In e-commerce systems, the specification and the program are usually developed together.

- Some fundamental principles apply to all types of software system, irrespective of the development techniques used:
  - Systems should be developed using a managed and understood development process.
  - Dependability and performance are important for all types of system.
  - Understanding and managing the software specification and requirements (what the software should do) are important.
  - Where appropriate, you should reuse software that has already been developed rather than write new software.

YouTube video : **TYPES OF SOFTWARE**

<https://www.youtube.com/watch?v=BTB86HeZVwk>

- **Heterogeneity**
  - Increasingly, systems are required to operate as distributed systems across networks that include different types of computer and mobile devices.
- **Business and social change**
  - Business and society are changing incredibly quickly as emerging economies develop and new technologies become available. They need to be able to change their existing software and to rapidly develop new software.
- **Security and trust**
  - As software is intertwined with all aspects of our lives, it is essential that we can trust that software.

# Why software engineering important?

Xi'an Jiaotong-Liverpool University

西交利物浦大學

- More and more, individuals and society rely on advanced software systems. We need to be able to produce reliable and trustworthy systems economically and quickly.
- It is usually cheaper, in the long run, to use software engineering methods and techniques for software systems rather than just write the programs as if it was a personal programming project. For most types of systems, the majority of costs are the costs of changing the software after it has gone into use.

# Software engineering and the web

- The Web is now a platform for running application and organizations are increasingly developing web-based systems rather than local systems.
- Web services allow application functionality to be accessed over the web.
- Cloud computing is an approach to the provision of computer services where applications run remotely on the 'cloud'.
  - Users do not buy software but pay according to use.

- Software reuse is the dominant approach for constructing web-based systems.
  - When building these systems, you think about how you can assemble them from pre-existing software components and systems.
- Web-based systems should be developed and delivered incrementally.
  - It is now generally recognized that it is impractical to specify all the requirements for such systems in advance.
- User interfaces are constrained by the capabilities of web browsers.
  - Technologies such as AJAX allow rich interfaces to be created within a web browser but are still difficult to use. Web forms with local scripting are more commonly used.

*"With great power comes  
great responsibility"*  
,\_Voltaire

**With Great Power**

**Comes  
great responsibility**

- Ethics, as understood here, addresses any intentional action that impacts negatively or positively the lives and values of others.
- The ethical activity involved in technical decisions should be based on an understanding of the impact of those decisions.
- “Software engineers have obligations to the users of their products, which include not only the implemented system but also includes other products such as requirements, software project management plans, specifications, designs, documentation, test suites, programs, user manuals, and training materials” (Software Engineering Ethics, Donald Gotterbarn)

## Additional reading

**The Software Engineering Code of Ethics and Professional Practice**

<https://www.youtube.com/watch?v=c0cXP9XLZbY>

- You must also behave in an ethical and morally responsible way if you are to be respected as a professional engineer.
- You should not use your skills and abilities to behave in a dishonest way or in a way that will bring disrepute to the software engineering profession.

- There are areas where standards of acceptable behavior are not bound by laws but by the more tenuous notion of professional responsibility. Some of these are:
  - Confidentiality
  - Competence
  - Intellectual property rights
  - Computer misuse

# Software development risk

- Many software development projects run into difficulties
  - Does not work as expected
  - Over budget
  - Late delivery
- Much of the functionalities in the software is wasted
  - Wrong requirement
  - User dislike it
  - There are no customer
  - etc

- Many software projects fail because the software developers build the wrong software. The software development team must: -
  - Fully understand requirement
  - Validate requirement
- The developer will often add technical insights and suggestions, but remember the client satisfaction is the primary measurement of success in software project.

# Software Development Risk –

## The danger

- Failures of software development projects can bankrupt companies.
- What are the consequences if the development of a software: -
  - Late?
  - Over budget?
  - Does not work or full of bugs?

# Software Engineering vs Computer Science

## Software Engineering

- Concerned with the practicalities of developing and delivery professional software system

## Computer Science

- Focuses on the theory and fundamentals

- software engineering and its importance
- development of different types of software systems and
- the required different software engineering techniques
- ethical and professional issues in software engineering
